

COMP9444: Neural Networks and Deep Learning

Week 2c. PyTorch

Alan Blair

School of Computer Science and Engineering

June 9, 2025

Typical Structure of a PyTorch Program

```
# create neural network
net = MyNetwork().to(device) # CPU or GPU

# prepare to load the training and test data
train_loader = torch.utils.data.DataLoader(...)
test_loader = torch.utils.data.DataLoader(...)

# choose between SGD, Adam or other optimizer
optimizer = torch.optim.SGD(net.parameters,...)

for epoch in range(1, epochs): # training loop
    train(args, net, device, train_loader, optimizer)
    # periodically evaluate network on test data
    if epoch % 10 == 0:
        test( args, net, device, test_loader)
```

Defining a Network Structure

```
class MyNetwork(torch.nn.Module):  
  
    def __init__(self):  
        super(MyNetwork, self).__init__()  
        # define structure of the network here  
  
    def forward(self, input):  
        # apply network and return output
```

Defining a Custom Model

This module computes a function of the form $(x, y) \mapsto Ax \log(y) + By^2$

```
import torch.nn as nn
```

```
class MyModel(nn.Module):
```

```
    def __init__(self):
```

```
        super(MyModel, self).__init__()
```

```
        self.A = nn.Parameter(torch.randn((1),requires_grad=True))
```

```
        self.B = nn.Parameter(torch.randn((1),requires_grad=True))
```

```
    def forward(self, input):
```

```
        output = self.A * input[:,0] * torch.log(input[:,1]) \
            + self.B * input[:,1] * input[:,1]
```

```
        return output
```

Building a Net from Individual Components

```
class MyModel(torch.nn.Module):  
  
    def __init__(self):  
        super(MyModel, self).__init__()  
        self.in_to_hid = torch.nn.Linear(2,2)  
        self.hid_to_out = torch.nn.Linear(2,1)  
  
    def forward(self, input):  
        hid_sum = self.in_to_hid(input)  
        hidden = torch.tanh(hid_sum)  
        out_sum = self.hid_to_out(hidden)  
        output = torch.sigmoid(out_sum)  
        return output
```

Defining a Sequential Network

```
class MyModel(torch.nn.Module):  
  
    def __init__(self, num_input, num_hid, num_out):  
        super(MyModel, self).__init__()  
        self.main = nn.Sequential(  
            nn.Linear(num_input, num_hid),  
            nn.Tanh(),  
            nn.Linear(num_hid, num_out),  
            nn.Sigmoid()  
        )  
  
    def forward(self, input):  
        output = self.main(input)  
        return output
```

Sequential Components

Network layers:

- `nn.Linear()`
- `nn.Conv2d()` (Week 4)

Intermediate Operators:

- `nn.Dropout()`
- `nn.BatchNorm()` (Week 4)

Activation Functions:

- `nn.Sigmoid()`
- `nn.Tanh()`
- `nn.ReLU()`

Declaring Data Explicitly

```
import torch.utils.data

# input and target values for the XOR task
input = torch.Tensor([[0,0],[0,1],[1,0],[1,1]])
target = torch.Tensor([[0],[1],[1],[0]])

xdata = torch.utils.data.TensorDataset(input,target)
train_loader = torch.utils.data.DataLoader(xdata,batch_size=4)
```

Loading Data from a .csv File

```
import pandas as pd

df = pd.read_csv("sonar.all-data.csv")
df = df.replace('R',0)
df = df.replace('M',1)
data = torch.tensor(df.values, dtype=torch.float32)
num_input = data.shape[1] - 1
input = data[:,0:num_input]
target = data[:,num_input:num_input+1]
dataset = torch.utils.data.TensorDataset(input, target)
```

Custom Datasets

```
from data import ImageFolder

# load images from a specified directory
dataset = ImageFolder(folder, transform)

import torchvision.datasets as dsets

# download popular image datasets remotely
mnistset = dsets.MNIST(...)
cifarset = dsets.CIFAR10(...)
celebset = dsets.CelebA(...)
```

Choosing an Optimizer

```
# SGD stands for "Stochastic Gradient Descent"  
optimizer = torch.optim.SGD( net.parameters(),  
    lr=0.01, momentum=0.9,  
    weight_decay=0.0001)
```

```
# Adam = Adaptive Moment Estimation (good for deep networks)  
optimizer = torch.optim.Adam(net.parameters(),eps=0.000001,  
    lr=0.01, betas=(0.5,0.999),  
    weight_decay=0.0001)
```

Training

```
def train(args, net, device, train_loader, optimizer):  
  
    for batch_idx, (data,target) in enumerate(train_loader):  
  
        optimizer.zero_grad()    # zero the gradients  
        output = net(data)        # apply network  
        loss = ...                # compute loss function  
        loss.backward()           # compute gradients  
        optimizer.step()          # update weights
```

Loss Functions

```
loss = torch.sum((output-target)*(output-target))  
loss = F.nll_loss(output,target)                # (Week 3)  
loss = F.binary_cross_entropy(output,target)    # (Week 3)  
loss = F.softmax(output,dim=1)                  # (Week 3)  
loss = F.log_softmax(output,dim=1)              # (Week 3)
```

Testing

```
def test(args, net, device, test_loader):  
  
    with torch.no_grad(): # suppress updating of gradients  
        net.eval() # toggle batch norm, dropout  
        for data, target in test_loader:  
            output = model(data)  
            test_loss = ...  
            print(test_loss)  
  
    net.train() # toggle batch norm, dropout back again
```

Computational Graphs

PyTorch automatically builds a computational graph, enabling it to backpropagate derivatives.

Every parameter includes `.data` and `.grad` components, for example:

`A.data`

`A.grad`

`optimizer.zero_grad()` sets all `.grad` components to zero.

`loss.backward()` updates the `.grad` component of all Parameters by backpropagating gradients through the computational graph.

`optimizer.step()` updates the `.data` components.

Controlling the Computational Graph

If we need to stop the gradients from being backpropagated through a certain variable (or expression) `A`, we can exclude it from the computational graph by using:

```
A.detach()
```

By default, `loss.backward()` discards the computational graph after computing the gradients.

If needed, we can force it to keep the computational graph by calling it this way:

```
loss.backward(retain_graph=True)
```
